Elastic Net Models

Walter K. Kremers, Mayo Clinic, Rochester MN

18 August 2025

Introduction

From our experience the relaxed lasso models involving a wieghted average of coefficients between the fully penalized lasso model and the unpenalized regression model based upon the non zero terms (from the penalized lasso model) generally provides a balance bewteen good fit and parsimony (fewer terms and so a simpler model). We understand may find advantage of the elastic net model which also involves a weighted average between a penalized and unpanalized regression models but allows for the penalty to involve a combination of L1 and L2 distance measures (See the vignette "An Introduction to glmnet" at https://CRAN.R-project.org/package=glmnet).

To allow one to investigate how the elastic net model may benefit their data the nested.glmnetr() program can fit elastic net models for multiple values of both alpha, the mixing parameter for the L1 and L2 penalty metics, and gamma, the mixing parameter between the penalzed and unpenalzed fits. As for the other models the nested.glmnetr() function performs a "simple" nested cross validation of the elastic net model in parallel with all other fitted models, even if not involving all the advantages of the nested cross validation described by Bates, Hastie and Tibshirani.

In addition to comparing the nested cross validation performances of deviances, agreement and calibration one can graphically inspect the (non nested) cross validation deviance values for the candidate models as function of each of the alpha, gamma and lambda.

An example dataset

To demonstrate usage of *cv.stepreg* we first generate a data set for analysis, run an analysis and evaluate. Following the *Using glmnetr* vignette, the code

```
# Simulate data for use in an example survival model fit
# first, optionally, assign a seed for random number generation to get applicable results
set.seed(116291950)
simdata=glmnetr.simdata(nrows=1000, ncols=100, beta=NULL)
```

generates simulated data for analysis. We extract data in the format required for input to the nested.glmnetr (and glmnetr) programs.

```
# Extract simulated survival data
xs = simdata$xs  # matrix of predictors
y_ = simdata$y_  # vector of numerical responses
```

Inspecting the predictor matrix and outcome vector we see

```
# Check the sample size and number of predictors
print(dim(xs))
## [1] 1000 100
# Check the rank of the design matrix, i.e. the degrees of freedom in the predictors
Matrix::rankMatrix(xs)[[1]]
## [1] 94
# Inspect the first few rows and some select columns
print(round(xs[1:10,c(1:12,18:20)],digits=6))

Fitting an Elastic Net model

To fit the elastic net model we call the neted.glmnetr() function line in the "An Introduction to glmnetr" while now specifying a vector of candidate alpha values using the alpha option in the function call. For comparison we are also fitting the random forest model as well as the full model including all candiate predictors.

```
## ## seed$seedr[1] = 791590258
```

When alpha is not specified the value c(1) is used to fit models based only on the L1 penalty. By default the candidate values for gamma are c(0, 0.25, 0.5, 0.75, 1), as suggested in the glmnet package.

Naive DevRat Naive R-square Non Zero

Model deviance ratios, measures of agreement (r-square or concordance) and linear calibration coefficients obtained from nested cross validation can be displayed graphically, including values from calculated from individual fold values, the averages over the folds and the naive values obtained basing caculations on the training data are displayed. Here we present only the figure for deviance ratios.

```
# Fit a relaxed lasso model informed by cross validation plot(nested_elastic_fit, ylim=c(0.6,0.95))
```

Graphical presentations of cross validation deviances

```
# Fit a relaxed lasso model informed by cross validation
plot(nested_elastic_fit , type="elastic")
```

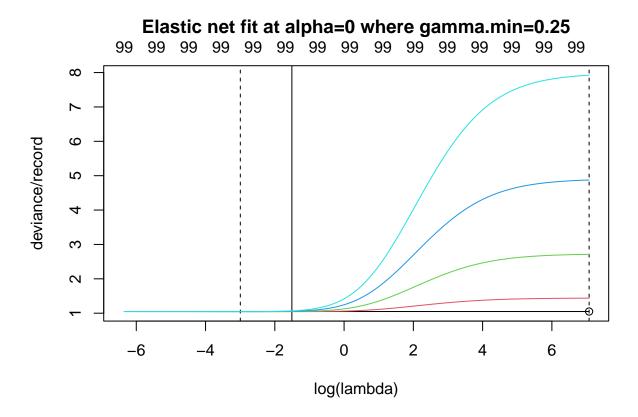

Elastic Net tuned for alpha, gamma and lambda minimizing CV average deviance (maximizing log likelih ## alpha.min= 1, gamma.min = 1, log(lambda) = -3.74, df = 59, deviance = 1.0081

Here we see that all curves for differnt values of gamma are for the same loss minimizing value for alpha of 1. We can also plot the curves for other values of alpha, for eample 0 corresponding to a pure L2 penaly.

```
# Fit a relaxed lasso model informed by cross validation
plot(nested_elastic_fit , type="elastic", alpha = 0)
```

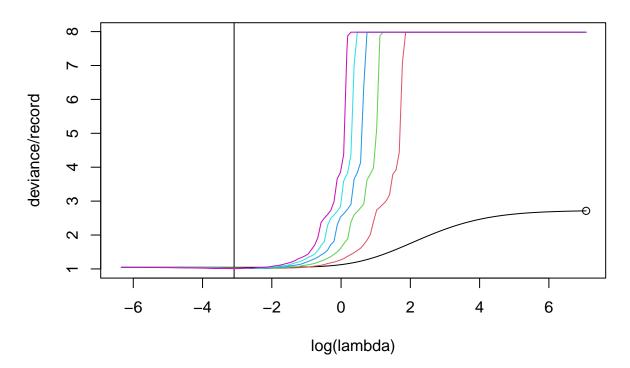

Elastic Net at alpha = 0 tuned for gamma and lambda minimizing CV average deviance (maximizing log l gamma.min = 0.25, log(lambda) = -1.507, df = 99, deviance = 1.0468

We can also plot the deviance curves for different values of alpha when specifying a single value for gamma.

```
# Fit a relaxed lasso model informed by cross validation
plot(nested_elastic_fit , type="elastic", gamma = 0.5)
```

Elastic net fit at gamma = 0.5 where alpha.min = 1

Elastic Net at gamma = 0.5 tuned for alpha and lambda minimizing CV average deviance (maximizing log ## alpha.min = 1, log(lambda) = -3.088, df = 34, deviance = 1.0097

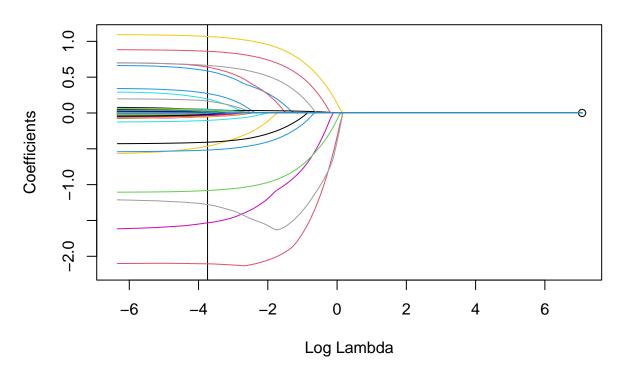

Graphical presentations of beta estimates

Similary we can plot the beta estimates for the optimizing values for alpha and gamma as a function of lambda.

```
# Fit a relaxed lasso model informed by cross validation
plot(nested_elastic_fit , type="elastic", coefs=1)

## For Elastic net fit where alpha.min = 1 and gamma.min = 1,
## log(lambda.min) = -3.74
```

Elastic net fit where alpha.min=1 and gamma.min = 1

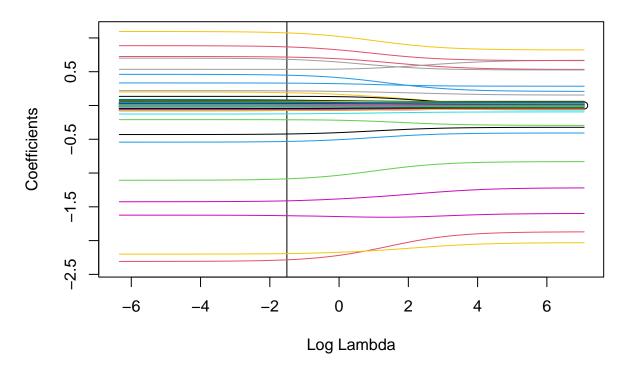

Similary we can plot beta's for other values of alpha and gamma, specifying eihter alpha, gamma or both. If we spedify only one of alpha or gamma, the plot will search for the other value minimizing the cross validation deviance.

```
# Fit a relaxed lasso model informed by cross validation
plot(nested_elastic_fit , type="elastic", coefs=1, alpha=0)
```

```
## For elastic net fit at alpha = 0
## gamma.min = 0.25 and log(lambda.min) = -1.5072
```

corresponding to relaxed model restricing the penalty to the L2 metric.

Numerical values for beta and predicteds

To extract beta's or calculate predicteds we use the predict() function. By default predictions are given for the lasso model. Alternatively one may specify th model type as "lasso", "elastic" or "ridge".

```
# get betas
betas = predict(nested_elastic_fit)
##
      gamma.min = 1
                       lambda.min = 0.02375409
                                                    df = 60
                                                              deviance = 1.0081
betas

            X89
  1.915120e-02 1.665664e-02 -1.928284e-02 -1.966950e-02 -2.162884e-03
# predicteds ...
preds = predict(nested_elastic_fit , xs)
##
                     lambda.min = 0.02375409
                                                deviance = 1.0081
      gamma.min = 1
preds[1:10]
   [1] -2.10768002 -0.06914494 1.48003175 2.03594328 3.31801993 -2.40537916
   [7] 1.21440489 0.71834394 0.21372610 -0.86953425
```

For this case the best lasso model is the "fully" penalized (relaxed) lasso model.

```
# get betas ...
betas = predict(nested_elastic_fit, type="elastic" )
betas

# predicteds ...
preds = predict(nested_elastic_fit , xs, type="elastic" )
preds[1:10]
```

For this analysis the best elastic net model is the same as the best lasso model, so we suppressed here the printing out of the same numbers.
